ANALYTICAL GRADIENTS OF THE OPTIMIZATION

In this section, we introduce the key analytical gradients of the trajectory optimization problem.

A. Preliminaries

According to the theory of Lie groups and Lie algebra for robotics [\[1\]](#page-1-0), [\[2\]](#page-1-1), we denote the conversion from the axis-angle rotation vector $r \in \mathfrak{so}(3)$ to the rotation matrix $\mathbf{R} \in SO(3)$ as $\mathbf{R} = \exp(\mathbf{r}^{\wedge})$, and the inverse conversion is denoted as $\bm{r} = \ln(\bm{R})^\vee.$

According to the linear approximation of the Baker-Campbell-Hausdorff (BCH) formula [\[3\]](#page-1-2), we have

$$
\ln(\exp(r_1^{\wedge})\exp(r_2^{\wedge}))^{\vee} \approx \left\{ \begin{array}{c} J_l(r_2)^{-1}r_1 + r_2, \text{ when } r_1 \to 0, \\ J_r(r_1)^{-1}r_2 + r_1, \text{ when } r_2 \to 0. \\ 1) \end{array} \right.
$$

Here, $J_r(r) = J_l(-r)$, and $J_l(r)$ can be calculated as

$$
J_l(r) = \frac{\sin \theta}{\theta} I + \left(1 - \frac{\sin \theta}{\theta}\right) a a^{\mathsf{T}} + \frac{1 - \cos \theta}{\theta} a^{\wedge}, \quad (2)
$$

$$
J_l(r)^{-1} = \frac{\theta}{2} \cot \frac{\theta}{2} I + \left(1 - \frac{\theta}{2} \cot \frac{\theta}{2}\right) a a^{\mathsf{T}} - \frac{\theta}{2} a^{\wedge}, \quad (3)
$$

where θ and α are the angle and axis of r, respectively.

B. Gradients of Orientation Distances

Here we generally introduce the gradient regarding the orientation distance. We define the weighted scalar distance of orientations R and R_d as

$$
d_{\mathrm{r}}(\boldsymbol{R}, \boldsymbol{R}_{\mathrm{d}}, \boldsymbol{W}_{\mathrm{r}}) = \frac{1}{2} \boldsymbol{r}_{\mathrm{e}}^{\mathsf{T}} \boldsymbol{W}_{\mathrm{r}} \boldsymbol{r}_{\mathrm{e}},\tag{4}
$$

where r_e is defined as $\ln \left(RR_d^{-1}\right)^\vee$. Note that r_e is defined in the world frame W . In addition, W_r is a semi-positive definite matrix for weighting. Here, \boldsymbol{R} is determined by a variable x, and R_d is a constant desired orientation. Note that r_e is defined in the same frame as R and R_d .

In the following derivation, for convenience, we use both $\mathbf{R} \in \text{SO}(3)$ and $\mathbf{r} \in \mathfrak{so}(3)$ to represent the same rotation; e.g., $\boldsymbol{R} = \exp(\boldsymbol{r}^{\wedge})$ and $\boldsymbol{R}_{\mathrm{d}} = \exp(\boldsymbol{r}_{\mathrm{d}}^{\wedge}).$

The gradient of d_r w.r.t. the variable x is derived as

$$
\frac{\partial d_{\rm r}}{\partial x} = \frac{\partial d_{\rm r}}{\partial r_{\rm e}} \frac{\partial r_{\rm e}}{\partial x} = \frac{\partial d_{\rm r}}{\partial r_{\rm e}} \frac{\partial r_{\rm e}}{\partial \varphi} \frac{\partial \varphi}{\partial x} \tag{5}
$$

For convenience of the following calculation, here we introduce a perturbation variable $\varphi \in \mathfrak{so}(3)$, which means that we left perturb R by ΔR (i.e., $(\Delta R)R$), where $\Delta R = \exp(\varphi^{\wedge})$.

First, it is easy to obtain

$$
\frac{\partial d_{\rm r}}{\partial \boldsymbol{r}_{\rm e}} = \boldsymbol{r}_{\rm e}^{\mathsf{T}} \boldsymbol{W}_{\rm r} \tag{6}
$$

Second, regarding $\frac{\partial \mathbf{r}_{\cdot}}{\partial \varphi}$, we have

$$
\frac{\partial \mathbf{r}_{\mathbf{e}}}{\partial \varphi} = \lim_{\varphi \to 0} \frac{\ln \left(\exp(\varphi^{\wedge}) \exp(\mathbf{r}_{\mathbf{d}}^{\wedge}) \right)^{-1} \right)^{\vee}}{\varphi}
$$
\n
$$
- \frac{\ln \left(\exp(\mathbf{r}^{\wedge}) \left(\exp(\mathbf{r}_{\mathbf{d}}^{\wedge}) \right)^{-1} \right)^{\vee}}{\varphi}
$$
\n
$$
= \lim_{\varphi \to 0} \frac{\ln \left(\exp(\varphi^{\wedge}) \exp(\mathbf{r}_{\mathbf{e}}^{\wedge}) \right)^{\vee} - \ln \left(\exp(\mathbf{r}_{\mathbf{e}}^{\wedge}) \right)^{\vee}}{\varphi}
$$
\n(7)

It follows from the BCH formula [\(1\)](#page-0-0) that

$$
\frac{\partial \boldsymbol{r}_{\mathrm{e}}}{\partial \boldsymbol{\varphi}} = \lim_{\boldsymbol{\varphi} \to \mathbf{0}} \frac{\boldsymbol{J}_l(\boldsymbol{r}_{\mathrm{e}})^{-1} \boldsymbol{\varphi} + \boldsymbol{r}_{\mathrm{e}} - \boldsymbol{r}_{\mathrm{e}}}{\boldsymbol{\varphi}} = \boldsymbol{J}_l(\boldsymbol{r}_{\mathrm{e}})^{-1} \tag{8}
$$

We thus obtain $\frac{\partial d_r}{\partial \varphi} = r_e^{\mathsf{T}} W_r J_l(r_e)^{-1}$. Moreover, using [\(3\)](#page-0-1), we can obtain $r_{\rm e}^{\mathsf{T}} \dot{J}_l(r_{\rm e})^{-1} = r_{\rm e}^{\mathsf{T}}$. Thus, in special cases where the weights for each orientation dimension are the same (i.e., $W_{\rm r} = wI$, we further have $\frac{\partial d_{\rm r}}{\partial \varphi} = wr_{\rm e}^{\mathsf{T}} J_l(r_{\rm e})^{-1} = wr_{\rm e}^{\mathsf{T}}$.

Third, as the perturbation variable $\varphi \rightarrow 0$, we have $\frac{\partial \varphi}{\partial x} = J_{\rm a}(x)$, where $J_{\rm a}(x)$ is the space Jacobian that relates the spatial angular velocity to \dot{x} .

C. Gradients of Pose Distances

Similar to the derivation of the gradients of orientation distances, the general formula of the gradients of pose distances is derived as follows.

The weighted scalar distance between poses T and T_d is defined as

$$
d(\boldsymbol{T}, \boldsymbol{T}_{\mathrm{d}}, \boldsymbol{W}) = \frac{1}{2} \boldsymbol{e}^{\mathsf{T}} \boldsymbol{W} \boldsymbol{e}
$$
 (9)

where $e = [p_e; r_e]$, in which $p_e = p - p_d$ and $r_e =$ $\ln \left(\exp(r^{\wedge}) \left(\exp(r^{\wedge}_d) \right)^{-1} \right)^{\vee}$. Here, T is determined by a variable x , and T_d is a constant desired pose. Note that e is defined in the same frame as T and T_d .

Similar to [\(5\)](#page-0-2), we introduce a perturbation variable $\phi \in$ $\mathfrak{se}(3)$. Then, the gradient of d w.r.t. x is derived as

$$
\frac{\partial d}{\partial x} = \frac{\partial d}{\partial e} \frac{\partial e}{\partial \phi} \frac{\partial \phi}{\partial x}
$$
(10)

where $\frac{\partial d}{\partial \mathbf{e}} = \mathbf{e}^\mathsf{T} \mathbf{W}$ and

$$
\frac{\partial e}{\partial \phi} = \left[\begin{array}{cc} I & 0 \\ 0 & J_l(r_e)^{-1} \end{array} \right] \tag{11}
$$

Additionally, we have $\frac{\partial \phi}{\partial x} = J(x)$, where $J(x)$ is the space Jacobian that relates the spatial twist to \dot{x} .

D. Gradients of Jobject

It is easy to see that \mathcal{J}_{object} is only relevant to the object pose at time T. The gradient between the position distance cost and the object position variable is easy to derive. Here, we introduce the gradient regarding the orientation distance (i.e., $\frac{\partial d_r}{\partial r_{0,T}}$). For brevity, we omit the subscripts o and T.

Similar to [\(7\)](#page-0-3) and [\(8\)](#page-0-4), we derive that

$$
\frac{\partial \varphi}{\partial r} = \left(\frac{\partial r}{\partial \varphi}\right)^{-1} = J_l(r) \tag{12}
$$

We then have

$$
\frac{\partial d_{\rm r}}{\partial \boldsymbol{r}} = \boldsymbol{r}_{\rm e}^{\mathsf{T}} \boldsymbol{W}_{\rm r} \boldsymbol{J}_{l}(\boldsymbol{r}_{\rm e})^{-1} \frac{\partial \boldsymbol{\varphi}}{\partial \boldsymbol{r}} = \boldsymbol{r}_{\rm e}^{\mathsf{T}} \boldsymbol{W}_{\rm r} \boldsymbol{J}_{l}(\boldsymbol{r}_{\rm e})^{-1} \boldsymbol{J}_{l}(\boldsymbol{r}) \qquad (13)
$$

E. Gradients of $\mathcal{J}_{\text{finger}}$

We denote the Lie algebra corresponding to the object pose $T_{0,t} \in SE(3)$ as $\xi_{0,t} = [\mathbf{p}_{0,t}; \mathbf{r}_{0,t}] \in \mathfrak{se}(3)$, which is defined in *W*. The optimization variable related to $d({}^{\mathcal{O}}T_{i,t}, {}^{\mathcal{O}}T_{i,0}, W_{f})$ contains the object pose $\xi_{0,t}$ and finger joint angle $q_{i,t}$. For brevity, we omit the subscripts o , i , and t . We further denote $\vartheta=[\xi;q].$

We can use [\(10\)](#page-0-5) to calculate the gradient, but we still need to know the space Jacobian that relates the fingertip twist in $\mathcal O$ to $\dot{\vartheta}$. As the object frame ϑ is moving, this Jacobian is a relative Jacobian between the finger and object. We can calculate this relative Jacobian using individual manipulator Jacobians defined in W [[4\]](#page-1-3), in which we regard the object as a virtual manipulator. According to (2) in [[4\]](#page-1-3), the relative Jacobian between the fingertip twist in \hat{O} and $\hat{\theta}$ can be expressed as

$$
{}^{\mathcal{O}}J_{\mathrm{f}}(\vartheta) = \left[\begin{array}{cc} -{}^{\mathcal{O}}\Psi_{\mathrm{f}}{}^{\mathcal{O}}\Omega_{\mathrm{w}}J_{\mathrm{o}}(\xi) & {}^{\mathcal{O}}\Omega_{\mathrm{w}}J_{\mathrm{f}}(q) \end{array} \right], \qquad (14)
$$

where $J_{\mathrm{o}}(\xi)$ is the space Jacobian that relates the object's twist in W to $\hat{\xi}$, and $J_f(q)$ is the space Jacobian that relates the fingertip's twist in W to \dot{q} . Similar to [\(12\)](#page-0-6), it can be obtained that

$$
J_{\mathrm{o}}(\xi) = \left[\begin{array}{cc} I & 0 \\ 0 & J_{l}(r) \end{array} \right], \tag{15}
$$

where r refers to the object orientation in W . The finger Jacobian $J_f(\cdot)$ can be obtained from the finger's kinematics. The transformation matrices Ψ and Ω are defined as

$$
{}^{a}\Psi_{b} = \left[\begin{array}{cc} I & -S({}^{a}p_{b}) \\ 0 & I \end{array} \right], \quad {}^{a}\Omega_{b} = \left[\begin{array}{cc} {}^{a}R_{b} & 0 \\ 0 & {}^{a}R_{b} \end{array} \right], (16)
$$

where $S(p)$ refers to the skew-symmetric matrix of vector p.

F. Other Gradients

Other gradients, including the gradients of \mathcal{J}_{joint} and those of the constraints, can be easily derived. The details are omitted here for brevity.
